### **CS 480**

### Introduction to Artificial Intelligence

November 18th, 2021

### **Announcements / Reminders**

- Programming Assignment #02:
  - due on Tuesday, December 7th, at 11:00 PM CST
- Written Assignment #03:
  - due on Wednesday, December 1st, at 11:00 PM CST
- Final Exam:
  - Thursday, December 2nd, 2021 (during lecture time)

# **Plan for Today**

Casual Introduction to Reinforcement Learning

### **Main Machine Learning Categories**

### **Supervised learning**

Supervised learning is one of the most common techniques in machine learning. It is based on known relationship(s) and patterns within data (for example: relationship between inputs and outputs).

Frequently used types: regression, and classification.

### **Unsupervised learning**

Unsupervised learning involves finding underlying patterns within data. Typically used in clustering data points (similar customers, etc.)

### **Reinforcement learning**

Reinforcement learning is inspired by behavioral psychology. It is based on a rewarding / punishing an algorithm.

Rewards and punishments are based on algorithm's a c t i o n within its environment.

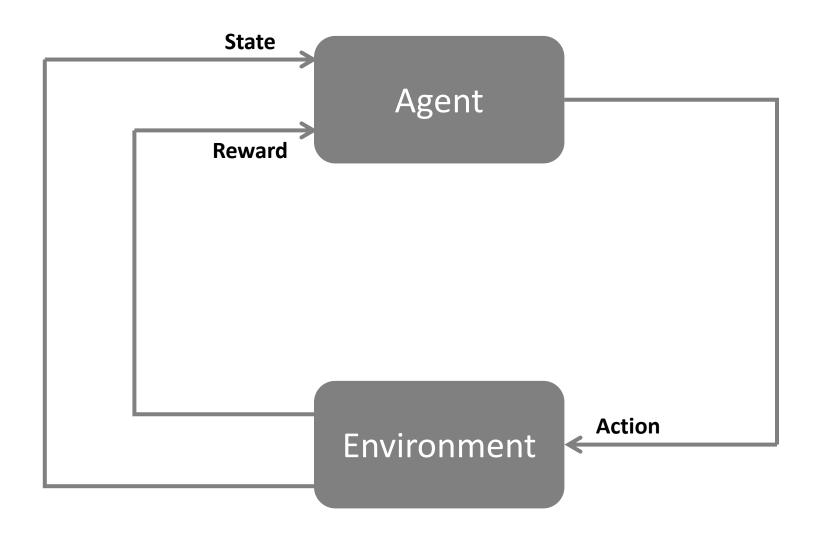

# What is Reinforcement Learning?

### Idea:

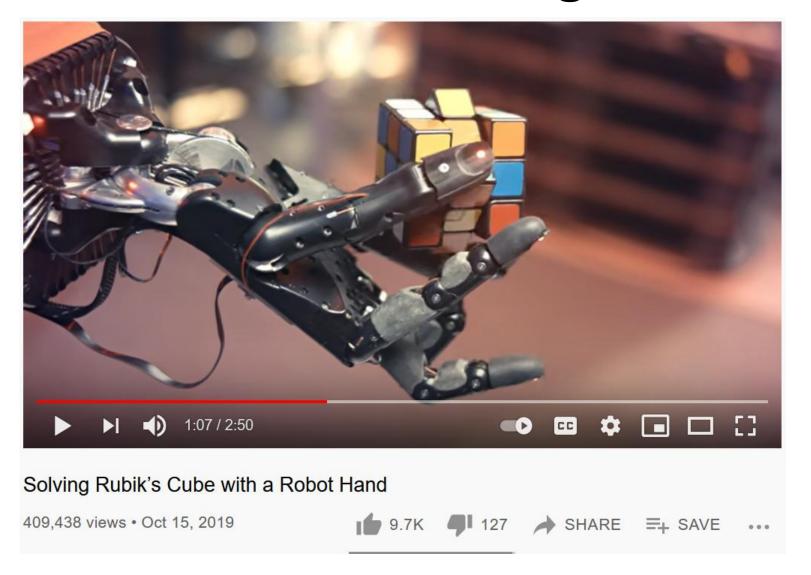

Reinforcement learning is inspired by behavioral psychology. It is based on a rewarding / punishing an algorithm.

Rewards and punishments are based on algorithm's action within its environment.

The K-armed bandit problem is a problem in which a fixed limited set of resources must be allocated between competing (alternative) choices in a way that maximizes their expected gain.

Each choice's properties are only partially known at the time of allocation, and may become better understood as time passes or by allocating resources to the choice.

In the problem, each machine provides a random reward from a probability distribution specific to that machine, that is not known a-priori.

The objective of the gambler is to maximize the sum of rewards earned through a sequence of lever pulls.

Bandit/Arm 1

33 %

current

success (win) rate

Bandit/Arm 2

52 %

current

success (win) rate

Bandit/Arm 3

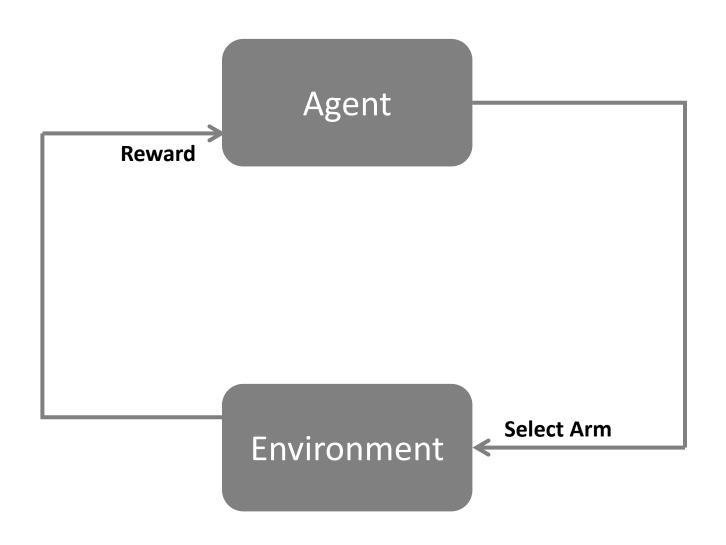

78 %

current

success (win) rate

Which bandit shall we play next?

### **K-Armed Bandit**

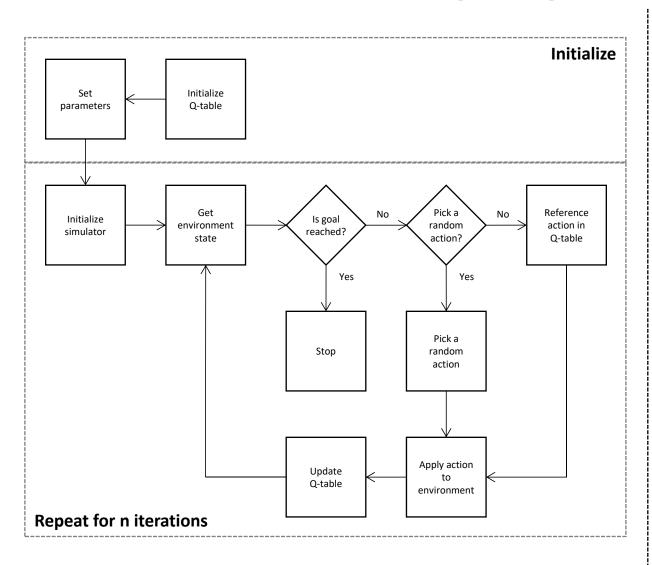

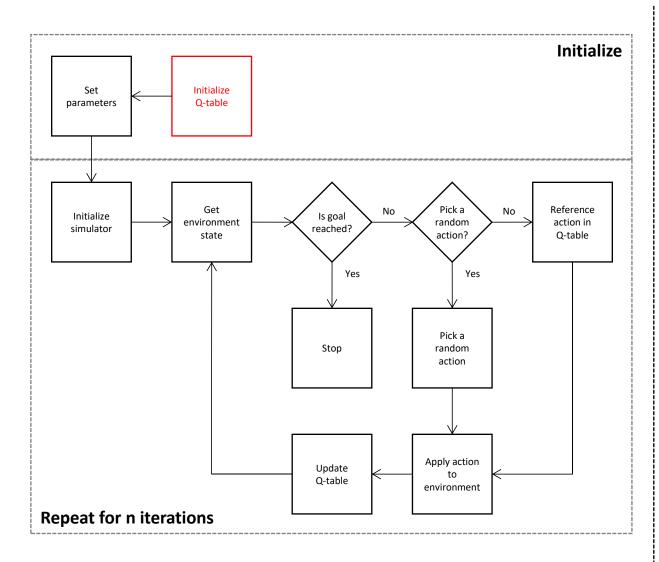

# **Exploration vs. Exploitation**

The crucial tradeoff the gambler faces at each trial is between "exploitation" of the machine that has the highest expected payoff and "exploration" to get more information about the expected payoffs of the other machines.

### ε-greedy Algorithm

```
generate random number p \in [0,1]
if (p < \varepsilon) // explore
    select random arm
                // exploit
else
    select current best arm
end
```

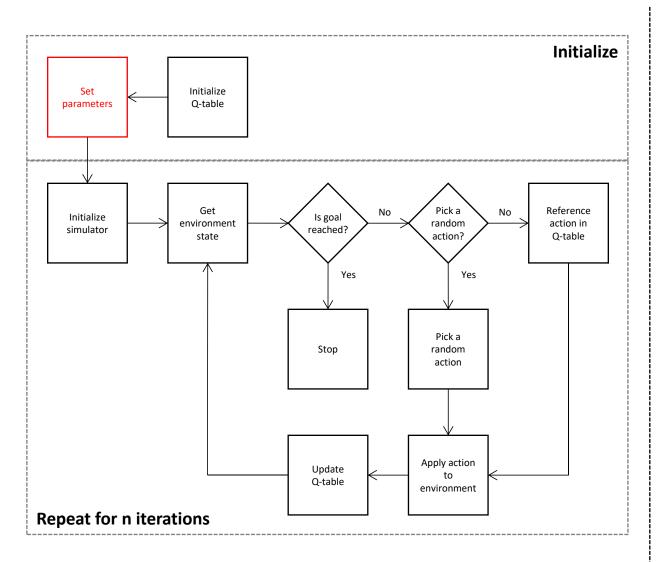

#### **Initialize Q-table:**

Set up and initialize (all values set to 0) a table where:

- rows represent possible states
- columns represent actions

Note that additional states can be added to the table when encountered.

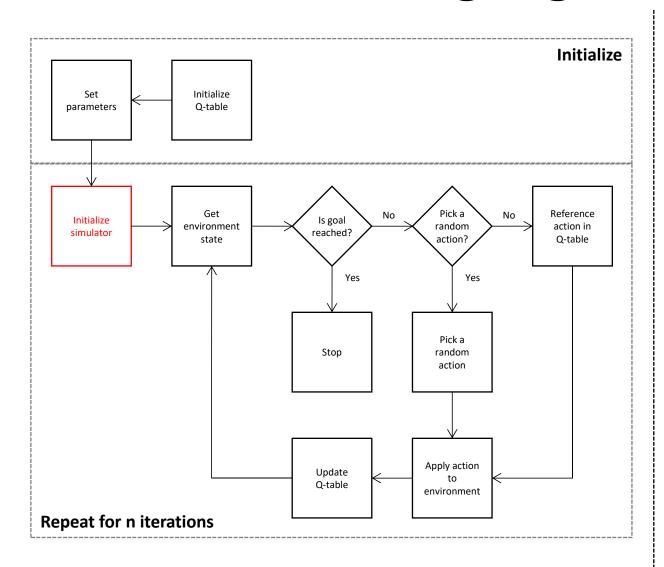

#### **Set parameters:**

Set and initialize **hyperparameters** for the Q-learning process.

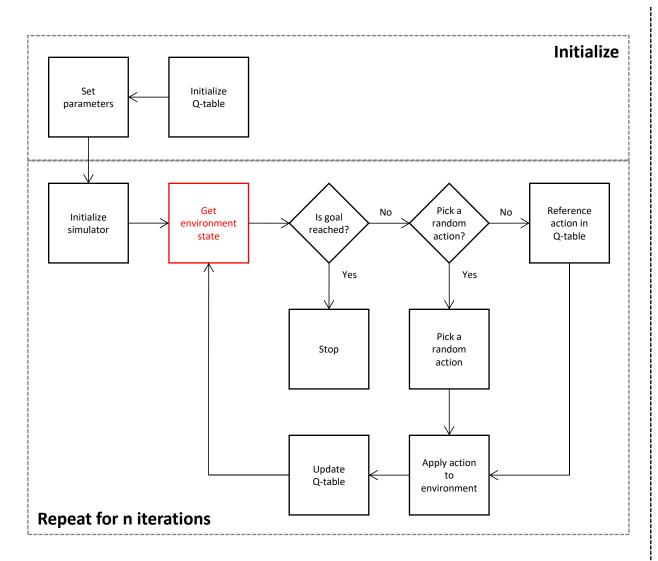

#### **Hyperparemeters** include:

- chance of choosing a random action: a threshold for choosing a random action over an action from the Q-table
- learning rate: a parameter that describes how quickly the algorithm should learn from rewards in different states
  - high: faster learning with erratic Q-table changes
  - low: gradual learning with possibly more iterations
- discount factor: a parameter that describes how valuable are future rewards. It tells the algorithm whether it should seek "immediate gratification" (small) or "long-term reward" (large)

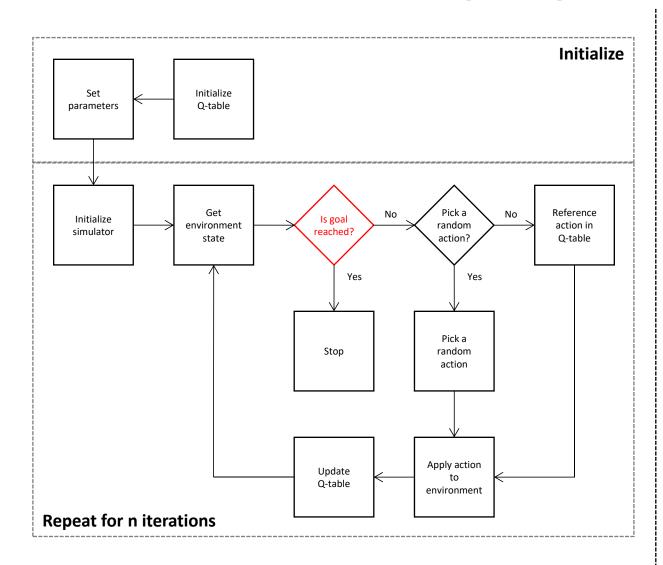

#### Initialize simulator:

Reset the simulated environment to its initial state and place the agent in a neutral state.

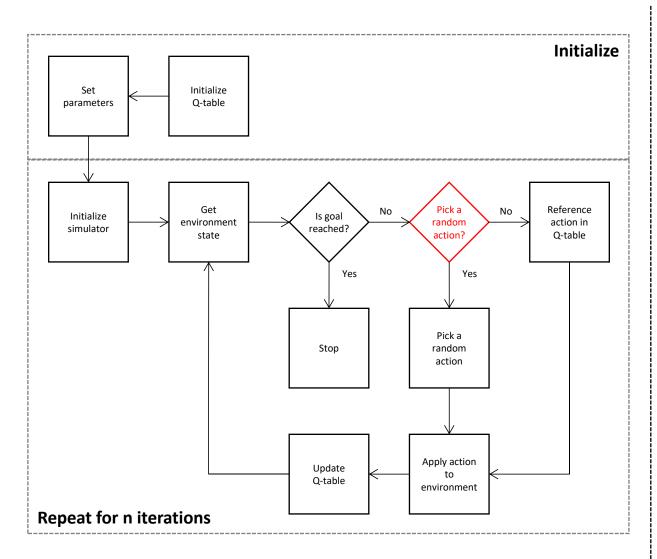

#### Get environment state:

Report the current state of the environment. Typically a vector of values representing all relevant variables.

#### Is goal reached?:

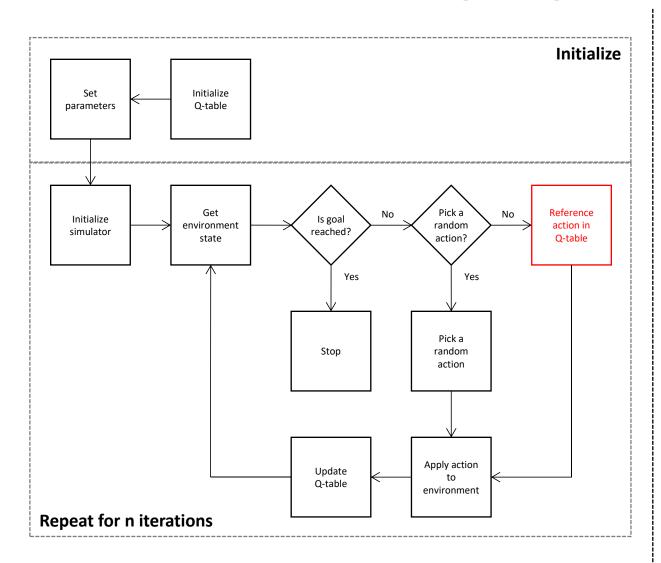

Verify if the goal of the simulation has been achieved. It could be decided with the agent arriving in expected final state or by some simulation parameter.

#### Pick a random action?:

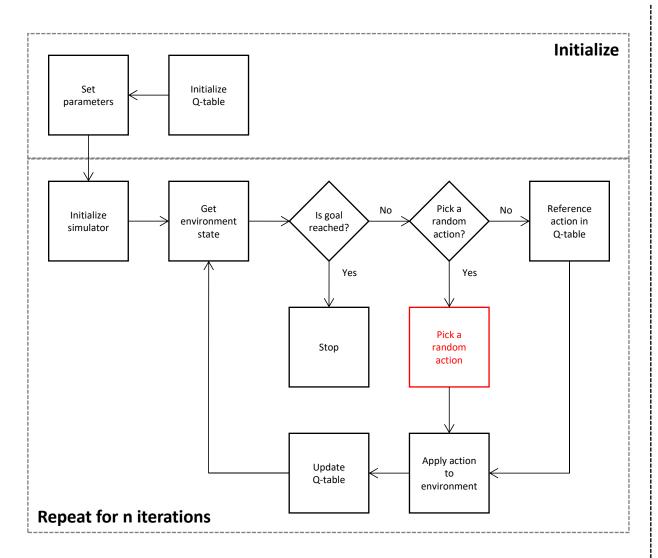

Decide whether next action should be picked at random or not (it will be selected based on Q-table data then).

Use the **chance of choosing a random action hyperparameter** to decide.

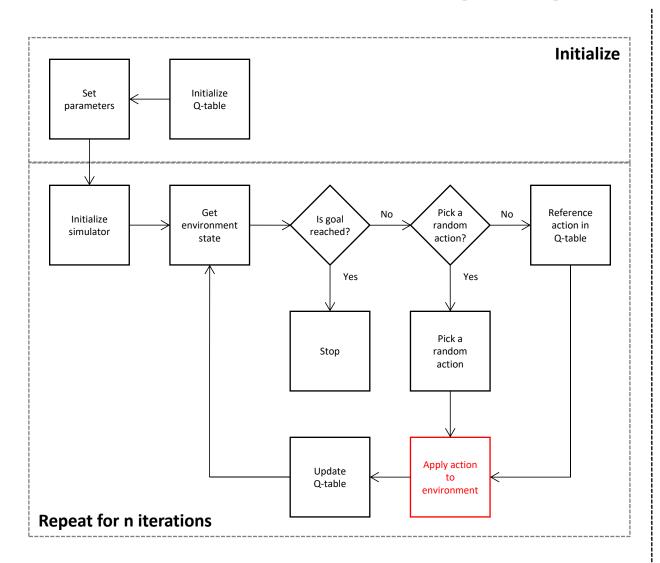

Reference action in Q-table:
Next action decision will be based on data from the Q-table given the

current state of the environment.

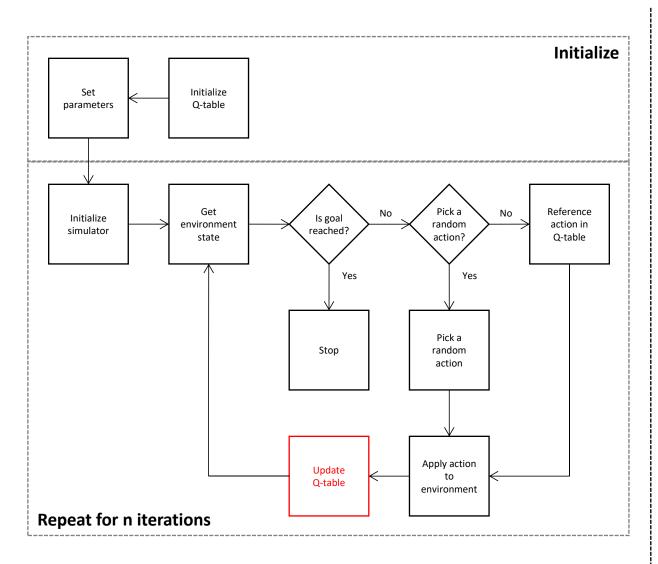

#### Pick a random action:

Pick any of the available actions at random. Helpful with exploration of the environment.

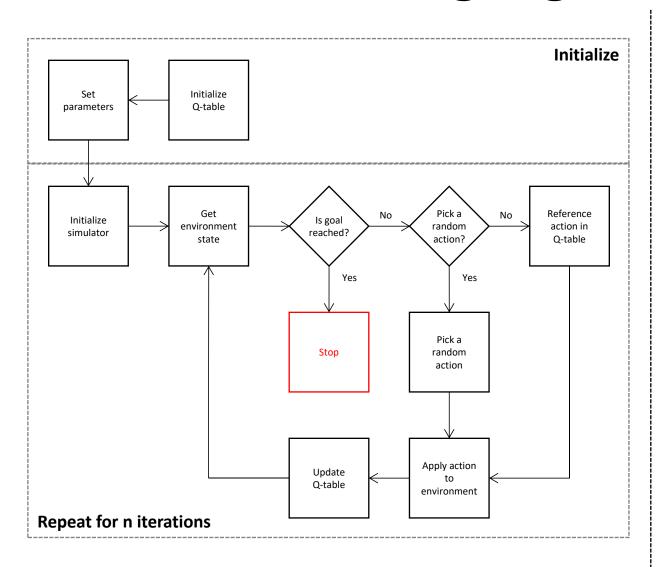

#### Apply action to environment:

Apply the action to the environment to change it. Each action will have its own reward.

#### **Update Q-table:**

Update the Q-table given the reward resulting from recently applied action (feedback from the environment).

Stop:

Stop the learning process
